Introduction

U-values (sometimes referred to as <u>heat transfer coefficients</u> or <u>thermal</u> <u>transmittances</u>) are used to <u>measure</u> how effective <u>elements of a building's</u> <u>fabric</u> are as insulators. That is, how effective they are at preventing <u>heat</u> from transmitting between the inside and the outside of a <u>building</u>.

<u>R-values</u>, which <u>measure thermal resistance</u> rather than thermal transmission, are often described as being the reciprocal of **U-values**, however, <u>R-values</u> do not include surface <u>heat transfers</u>.

The lower the **U-value** of an <u>element of a building's fabric</u>, the more slowly <u>heat</u> is able to transmit through it, and so the better it performs as an insulator.

Very broadly, the better (i.e. lower) the **U-value** of a <u>building's fabric</u>, the less <u>energy</u> is required to maintain comfortable <u>conditions</u> inside the <u>building</u>.

As <u>energy prices</u> increase, and there is greater awareness of <u>sustainability</u>, <u>performance measures</u> such as **U-values** have become more important, and <u>building standards</u> (such as the <u>Building Regulations</u>) have required that lower and lower **U-values** are achieved. This has required changes in the <u>design</u> of <u>buildings</u>, both in the use of <u>materials</u> (such as <u>insulation</u>), the make-up of the <u>building elements</u> (such as <u>cavity walls</u> and <u>double glazing</u>), and the overall make up of a <u>building's fabric</u> (for example, reducing the proportion of <u>glazing</u>).

Typical values

U-values are <u>measured</u> in <u>watts</u> per <u>square metre</u> per kelvin (W/(m²K)). For example, a <u>double glazed window</u> with a **U-value** of 2.8, for every degree difference in <u>temperature</u> between the inside and outside of the <u>window</u>, 2.8 <u>watts</u> will be transmitted every <u>square metre</u>.

A range of **U-values** are indicated below for the purposes of comparison only:

Solid <u>brick</u> wall: 2 W/(m²K)

- Cavity wall with no insulation: 1.5 W/(m²K).
- <u>Insulated</u> wall: 0.18 W/(m²K).
- Single glazing: 4.8 to 5.8 W/(m²K).
- Double glazing: 1.2 to 3.7 W/(m²K) depending on type.
- <u>Triple glazing</u> below: 1 W/(m²K).
- Solid <u>timber</u> door: 3 W/(m²K).

<u>Part L</u> of the <u>Building Regulations</u> (<u>Conservation</u> of <u>fuel</u> and <u>power</u>) now prevents certain <u>forms</u> of <u>construction</u> by setting limiting <u>standards</u> (i.e. maximum **U-values**) for <u>building elements</u>. See <u>Limiting fabric parameters</u> for more <u>information</u>.

It should be noted however that these are maximum permitted <u>values</u>, the <u>specification</u> for the notional <u>domestic building</u> referred to in Part L1A has considerably lower <u>values</u>, for example:

- External wall: 0.18 W/(m²K).
- Floor: 0.13 W/(m²K).
- Roofs: 0.13 W/(m²K).
- Windows, roof windows, glazed rooflights and glazed doors: 1.4
 W/(m²K).

See <u>Standard Assessment Procedure SAP</u> for more <u>information</u>.

NB: It is important to distinguish between **U-values** for <u>materials</u> (such as <u>glass</u>), or <u>assemblies</u> (such as <u>windows</u>, which have <u>frames</u>, air gaps, and so on), or <u>elements</u> (such as <u>walls</u>, which may have complex <u>constructions</u> comprising a number of different <u>components</u>).

Calculation

The U value of an element (in W/(m²K)) can be calculated from sum of the

thermal resistances (R-values in m²K/W) of the <u>layers</u> that make up the <u>element</u> plus its inside and outside surface <u>thermal resistances</u> (Ri and Ro).

U-value =
$$1/(\Sigma R + Ri + Ro)$$

Where the <u>thermal resistance</u> of the <u>layers</u> of the <u>element</u> R = the thickness of each <u>layer</u> / the <u>thermal conductivity</u> of that <u>layer</u> (its <u>k-value</u> or <u>lambda</u> <u>value</u> (λ) in W/(mK)).

This can become a complicated calculation when there are a large number of <u>layers</u>, <u>ventilated</u> or unventilated <u>cavities</u> are introduced, or the <u>element</u> is inclined. <u>Manufacturers</u> will generally provide **U-values** for <u>products</u> that they <u>supply</u>. There are also a number of **U-value** calculators available online (such as the <u>BRE U-value calculator</u>, although this is not free).

Calculation methods for **U-values** appropriate for demonstrating <u>compliance</u> with the <u>building regulations</u> are based on <u>standards</u> developed by the European Committee for <u>Standardisation</u> (CEN) and the <u>International Organisation for Standardisation</u> (ISO) and published as <u>British Standards</u>. See <u>Conventions for U-value calculations (2006 edition) BR 443</u>.

Whilst **U-values** are still used in the <u>Building Regulations</u> to set limiting <u>standards</u> for the <u>elements</u> of a <u>building's fabric</u>, the overall <u>thermal</u> <u>performance of buildings</u> is now assessed using more complex <u>modelling</u> procedures.

For non-domestic buildings, the <u>Simplified Building Energy Model</u> (<u>SBEM</u>) developed by the <u>BRE</u> for the <u>Department for Communities and Local</u> <u>Government</u>, determines the <u>energy performance</u> of a proposed <u>building</u> by comparing its annual <u>energy use</u> with that of a comparable <u>notional</u> <u>building</u>. <u>SBEM</u> can be downloaded from the <u>National Calculation</u> <u>Methodology website</u>.

For <u>dwellings</u>, <u>energy performance</u> is assessed using the <u>Government's</u> <u>Standard Assessment Procedure</u> (SAP).

NB: Whilst **U-values** and methods of <u>modelling</u> the <u>thermal performance of buildings</u> are invaluable in setting <u>standards</u> and providing a means of comparing alternative solutions, they are simplifications of reality, and <u>performance in use</u> rarely matches that which was predicted. Poor <u>workmanship</u> can result in reduced <u>thermal resistance</u>, as can poor detailing and the presence of <u>water</u> in <u>insulating materials</u>. See <u>Insulation</u> <u>specification</u> and <u>performance gap</u> for more <u>information</u>.

NB: The <u>building regulations</u> now require that '<u>consequential improvements</u>' are carried out on certain <u>non-domestic buildings</u> when they are extended or altered in order to bring the entire <u>building</u> more into line with the requirements of <u>Part L</u> of the <u>Building Regulations</u>. See <u>Consequential improvements</u> for more <u>information</u>.
